Hot-Swap Procedure for Unattached Physical Volumes	32
Removing a Ghost Disk using the PV Key	33
What is a Ghost Disk	
Removing a PV using its PV key	
Increasing the Root LV's size	37
Using Ignite/UX	37

Chapter 16	LVM
Using the Unofficial Procedure	37
LIF/BDRA Configuration Procedure	40
Commands Overview	41

# **Terminology**

The following abbreviations are common in LVM and will be used during this chapter:

VG = Volume Group LV = Logical Volume PV = Physical Volume

PVG = Physical Volume Group

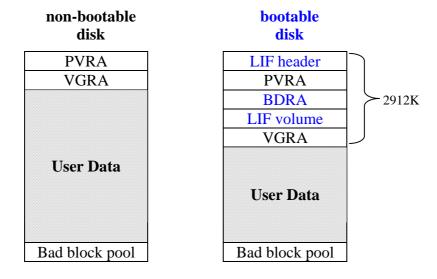

PE = Physical Extent LE = Logical Extent FS = File System

VGRA= Volume Group Reserved Area
VGDA= Volume Group Descriptor Area
VGSA = Volume Group Status Area
MCR = Mirror Consistency Record
PVRA = Physical Volume Reserved Area

BDRA = Boot Data Reserved Area

## **LVM Structural Information**

The LVM structural information resides in reserved areas (PVRA, VGRA) at the beginning of any LVM disk and is also called the *LVM header*. The following image shows the *on disk structure* of an LVM disk:

**NOTE:** the LVM header of a bootable disk is always **2912 KB**. The header size of a non-bootable disk is not fixed. It depends on the VG configuration parameters PVs/VG (-p max\_pv), PEs/PV (-e max\_pe) and LVs/VG (-l max\_lv), but it is usually smaller. The VG's VGRA must not be larger than a single extent..

**NOTE:** Itanium systems (UX 11.20, 11.22, 11.23) have a 100MB EFI partition at the beginning of the disk. Refer to the <u>Itanium Chapter</u> for details.

## **PVRA, BDRA and VGRA**

- 1. The **PVRA** is unique for every PV in the VG. It contains:
  - LVMREC describing the PV with e.g. PV-ID, VG-ID, PV number in VG, PE size; start and length of: VGRA, BDRA (if any), BBDIR, User Data and the Bad Block Pool; in case of a ServiceGuard Cluster the Cluster ID and information about the Cluster Lock Area.
  - BBDIR (Bad Block Directory, maintaining the Bad Block Pool).
- 2. The **BDRA** (only created with *pvcreate –B*) contains boot relevant information, e.g.:
  - Information about PVs in root VG
  - Information about Boot/Swap/Root LVs (major/minor numbers, etc.)
- 3. The **VGRA** is identical for any PV of the VG. It contains:
  - The VGDA describing the VG, with e.g.:
    - o VG-ID, configured max\_lv, max\_pv, max\_pe.
    - o per LV information: LV flags, size, schedule strategy, number of mirrors, stripes, stripe size, etc.
    - o per PV information: PV-ID, PV size, PV flags, Extent mapping, etc.
  - The VGSA containing information about missing PVs and stale extents.
  - The MCRs for Mirror Write Cache handling.

#### LIF Header and LIF Volume

LIF stands for *Logical Interchange Format*. The *LIF header* resides in the first 8 KB of any LVM boot disk. It contains the directory to the *LIF volume* that begins after the BDRA. It can be displayed using lifls(1M):

<pre># lifls -l /dev/rdsk/clt6d0 volume ISL10 data size 7984 directory size 8</pre>						
filename	type	start	size	implement	created	
=======	======	======	=======	=======	=======	
ISL	-12800	584	306	0	00/11/08	20:49:59
AUTO	-12289	896	1	0	00/11/08	20:49:59
HPUX	-12928	904	848	0	00/11/08	20:50:00
PAD	-12290	1752	1580	0	00/11/08	20:50:00
LABEL	BIN	3336	8	0	99/10/08	02:48:02

The LIF volume contains files necessary to boot: ISL, HPUX, LABEL and AUTO (for automatical boot). Look at the <u>Boot Chapter</u> in order to get a detailed explanation of each LIF file.

#### **PV-ID** and VG-ID

Any PV has a unique 8 byte long identifier - the PV-ID. The VG-ID is a unique identifier for the VG that this PV belongs to. It is also 8 byte long. Their values are stored in the PVRA.

The (contributed) utility **lvm** displays the complete LVM header:

Since the lvm tool may not always be available you can also read out PV-ID and VG-ID using standard commands that are available on any HP-UX system.

• How to use xd(1) to extract PV-ID and VG-ID:

```
# xd -j8200 -N16 -tu /dev/rdsk/c1t2d0
0000000 2000252410 965817345 2000252410 965817462
PV CPU-ID PV timestamp VG CPU-ID VG timestamp
```

The above information translates to:

- pvcreate and vgcreate was run on the system with systemID (uname –i) 2000252410
- pvcreate was run at timestamp 965817345 (seconds after Jan 1<sup>st</sup> 1970 0:00 UTC)
- vgcreate was run at timestamp 965817462 (117 seconds later)

or using adb(1):

```
    PV-ID:
        # echo "0d8200?UY" | adb /dev/dsk/c1t2d0
        2008: 2000252410 2000 Aug 9 12:35:45
    VG-ID:
        # echo "0d8208?UY" | adb /dev/dsk/c1t2d0
        2010: 2000252410 2000 Aug 9 12:37:42
```

# vgcfgbackup(1M)

A copy of the LVM header is held within the file system in the LVM backup file (/etc/lvmconf/\*.conf). Any modification of the LVM structure, e.g. through LVM commands like lvcreate, lvchange, vgextend, etc. will be automatically saved in the VGs config file through vgcfgbackup(1M).

You can run vgcfgbackup(1M) manually at any time:

```
# vgcfgbackup vgXY
Volume Group configuration for /dev/vgXY has been saved in
/etc/lvmconf/vgXY.conf
```

The content of the backup file is binary but you can use the -l option of vgcfgrestore(1M) to display at least the disks belonging to the VG:

```
# vgcfgrestore -1 -n vgXY
Volume Group Configuration information in "/etc/lvmconf/vgXY.conf"
VG Name /dev/vgXY
---- Physical volumes : 1 ----
/dev/rdsk/c1t6d0 (Bootable)
```

If the LVM header has been accidently overwritten or became corrupted on the disk you can recover it from this backup file using vgcfgrestore.

You usually use vgcfgrestore in case of a disk failure in order to write the LVM header from this backup file to the new disk:

```
# vgcfgrestore -n vgXY /dev/rdsk/c1t6d0
Volume Group configuration has been restored to /dev/rdsk/c1t6d0
```

**NOTE:** If you modify the LVM configuration but do not want the backup file to be updated, use "-A n" with the LVM command. Anyway - the previous configuration can be found in /etc/lvmconf/\*.conf.old.

**NOTE:** vgcfgrestore does not restore the LIF volume. This is done by mkboot.

## /etc/lvmtab and vgscan(1M)

The file /etc/lvmtab contains information about all known VGs and their PVs. It is mainly used by vgchange(1M) at VG activation time. lvmtab is a binary file but you can display the printable strings in that file using the strings(1M) command:

```
# strings /etc/lvmtab
/dev/vg00
/dev/dsk/c2t0d0
/dev/vgsap
/dev/dsk/c4t0d0
/dev/dsk/c5t0d0
/dev/dsk/c4t1d0
/dev/dsk/c5t1d0
/dev/vg01
/dev/dsk/c6t0d0
```

**NOTE:** this is only the "visible" part of the lymtab. It does also contain the VG-IDs, the total number of VGs, the number of PVs per VG and status information. Additional garbage characters printed by strings are not a problem as long as no important data is missing.

All VGs listed in lymtab are automatically activated during system startup. This is done in the script /sbin/lymrc, based upon configuration in /etc/lymrc.

If you do not trust the information in the lymtab anymore because it may have become corrupt somehow you can easily recreate it from PVRA and VGRA on the disks through the vgscan(1M) command. But be sure to save a copy before:

```
# cp /etc/lvmtab /etc/lvmtab.old
# vgscan -v
```

Warnings can usually be ignored.

**NOTE:** If you leave the original file in place then vgscan uses its contents for creating a new one. This may fail depending on the file's contents. You may then try to move the lymtab away. If there is no /etc/lymtab, then vgscan recreates it from the scratch. In this case information about currently deactivated VGs may be missing in the new file!

**ATTENTION:** On a ServiceGuard systems vgscan may fail. This is a known problem that is solved by LVM commands cumulative patches. The workaround is easy, just remove the file /dev/slvmvg before running vgscan.

**ATTENTION:** On systems using data replication products like BusinessCopy/XP, ContinousAccess/XP, EMC SRDF or EMC Timefinder vgscan may accidently add undesired PVs to VGs.

**NOTE:** vgscan does not take care about the order of alternate links! It may be necessary to switch the links afterwards (see section <u>PV Links</u> below).

## **Parameters and Limitations**

## LVM parameters

Parameter	Default	Maximum	set by
max. number of VGs	10	256	kernel tunable maxvgs
number of PVs per VG	16	255	vgcreate -p <max_pv></max_pv>
number of LVs per VG	255	255	vgcreate -l <max_lv></max_lv>
PE size (2 <sup>X</sup> )	4 MB	256 MB	vgcreate -s <pe_size></pe_size>
max. number of PE per PV	1016 PEs	65535 PEs	vgcreate -e <max_pe></max_pe>
max. number of PE per LV	0 PEs	65535 PEs	lvcreate -l <le_number></le_number>
LV size	0 MB	16 TB	lvcreate -L <mb></mb>

#### How the size of the VGRA is calculated

The VGRA size of any non-bootable disk must fit into the size of a single PE. For a bootable disk the VGRA needs to start at offset 2144K while user data always starts at offset 2912K. Due to these constraints the maximum VGRA size of bootable disks is even more restricted as for regular disks.

However, it is good to know how the size of the VGRA depends on the VG's configuration at creation time. The following set or formulas calculates vgra\_len in KB.

The ROUNDUP() function used above rounds up arg1 to a multiple of arg2.

The <u>lvmcompute</u> tool can be used to easily calculate the VGRA size and provides also table outputs like those shown in the following section. It is available from the HP internal site <u>ftp://einstein.grc.hp.com/TOOLS/LVM</u>.

## Maximum max\_pe values for non-boot disks

The following table lists the maximum allowed  $max\_pe$  (-e) values depending on  $max\_pv$  (-p) and  $pe\_size$  (-s) along with their resulting PV sizes in GB. Since the  $lv\_max$  parameter has a lower impact on the results, the table is caculated for  $lv\_max$ =255, which is default and also the worst-case. The fields for the default settings -s 4 -p 16 are shaded. Light shading indicates that the only restriction is the max. 65535 PE barrier for any given PV.

	PE size (vgcreate –s pe_size) in MB									
		1	2	4	8	16	32	64	128	256
	1	65535 64.0G	65535 128.0G	65535 256.0G	65535 512.0G	65535 1024.0G	65535 2048.0G	65535 4095.9G	65535 8191.9G	65535 16383.8G

## Supported JFS (VxFS) file and file system sizes

HP-UX	HP JFS	Veritas	Maximum	Maximum
Release	Version	Disk Layout	File Size	File System Size
UX 10.01	JFS 2.0	Version 2	2 GB	4 GB
	1	T	T	ı
UX 10.10	JFS 2.0	Version 2	2 GB	128 GB
	I	T	T	1
UX 10.20	JFS 3.0	Version 2	2 GB	128 GB
		Version 3	128GB	128 GB
UX 11.00	JFS 3.1	Version 2	2 GB	128 GB
		Version 3	1 TB	1 TB
	JFS 3.3	Version 2	2 GB	128 GB
		Version 3	1 TB	1 TB
		Version 4	1 TB	1 TB
		1	1	
UX 11.11	JFS 3.3	Version 2	2 GB	128 GB
	JFS 3.5	Version 3	2 TB	2 TB
		Version 4	2 TB	2 TB

**Bold font:** Default disk layouts for particular HP-UX Release/JFS version.

**NOTE:** For UX 11.00 with disk layout version 3 <u>PHKL 22719</u> (or newer) is needed to avoid mount problems if extending or creating file systems beyond 128 GB.

**NOTE:** Although it may be possible to create files or file systems larger than these documented limits, such files and file systems are not supported and the results of using them may be unpredictable.

# Supported HFS file and file system sizes

HP-UX	Maximum	Maximum
Release	File Size	File System Size
UX 10.01	2 GB	4 GB
UX 10.10	2 GB	128 GB
UX 10.20	128 GB	128 GB
UX 11.00	128 GB	128 GB
UX 11.11	128 GB	128 GB

NOTE: As of UX 10.20 it is possible to exceed the 128 GB limit to 256 GB, but it is not supported.

# **Display Commands**

To display information about VGs, LVs or PVs there is a set of commands available. Each of the commands provides an option -v to display detailed (verbos) output.

#### Information on VGs

```
# vgdisplay -v vg01
--- Volume groups ---
VG Name
                         /dev/vg01
VG Write Access
                         read/write
VG Status
                         available
Max LV
                         255
Cur LV
Open LV
                         1
Max PV
                         16
Cur PV
Act PV
Max PE per PV
                         1016
VGDA
PE Size (Mbytes)
Total PE
                         508
Alloc PE
                         508
Free PE
Total PVG
Total Spare PVs
                         0
Total Spare PVs in use 0
  --- Logical volumes ---
  LV Name
                           /dev/vg01/lvol1
  LV Status
                           available/syncd
  LV Size (Mbytes) 2032
                           508
  Current LE
  Allocated PE
                           508
  Used PV
                            1
  --- Physical volumes ---
  PV Name
                           /dev/dsk/c10t6d0
  PV Status
                           available
  Total PE
                            508
  Free PE
                            0
  Autoswitch
                            On
```

vgdisplay is useful to check wether the LVM configuration in memory is clean or not. First of all there should be no error messages. The status should be available or available/exclusive for ServiceGuard VGs. Cur PV should equal Act PV and Cur LV should be equal to Open LV.

## Information on PVs

```
# pvdisplay -v /dev/dsk/c0t6d0 | more
--- Physical volumes ---
```

```

. . .

None of the LEs/PEs should have a stale status.

# **LVM Basic Functionality**

## Adding a new PV / VG / LV

#### Adding a new PV

A disk has to be initialized before LVM can use it. The pvcreate command writes the PVRA to the disk and such a disk is called a PV:

```
# pvcreate /dev/rdsk/c0t5d0
```

If there is a valid PVRA already on the disk (it could have been used wit LVM before) you will get the following error message:

```
# pvcreate: The Physical Volume already belongs to a Volume Group
```

If you are sure the disk is free you can force the initialization using the -f option:

```
# pvcreate -f /dev/rdsk/c0t5d0
```

**NOTE:** For bootable disks you have to use the -B option additionally. This preserves the fixed 2912KB space for the LVM header (see section LVM structural information). You can find the procedure how to make a disk bootable in the section Mirroring the root disk later in this chapter.

To add the PV to an existing VG do:

```
# vgextend vg01 /dev/dsk/c0t5d0
# vgdisplay -v vg01
```

#### Adding a new VG

Here's how to create a new VG with 2 disks:

1) initialize the disk if not yet done:

```
# pvcreate [-f] /dev/rdsk/c0t5d0
# pvcreate [-f] /dev/rdsk/c0t6d0
```

2) select a unique minor number for the VG:

```
# 11 /dev/*/group

crw-r--r- 1 root sys 64 0x000000 Apr 4 2001 /dev/vg00/group

crw-r--r- 1 root sys 64 0x010000 Oct 26 15:52 /dev/vg01/group

crw-r--r- 1 root sys 64 0x020000 Aug 2 15:49 /dev/vgsap/group
```

3) create the VG control file (group file):

```
# mkdir /dev/vgnew
# mknod /dev/vgnew/group c 64 0x030000
```

**NOTE:** Starting with LVM commands patch <a href="PHCO\_24645">PHCO\_24645</a> (UX 11.00) or <a href="PHCO\_25814">PHCO\_25814</a> (UX 11.11) vgcreate and vgimport will check for the uniqueness of the group file's minor number.

- 4) create and display the VG:
  - # vgcreate vgnew /dev/dsk/c0t5d0 /dev/dsk/c0t6d0
  - # vgdisplay -v vgnew

NOTE: One of the VG's parameters is max\_pe, i.e the maximum number of physical extents this VG can handle per disk. The default value is 1016. Multiplying this with the default PE size of 4MB results in approx. 4GB disk space that can be handled by this VG. Adding a larger disk to this VG later is not possible. Believe me - there are absolutely no options to do this other than vgcreate! Anyway - vgcreate automatically adjusts max\_pe in order be able to handle the largest PV given in the arguments. Its always a good idea to set max\_pe explicitly to a value large enough to allow for future expansions. This can be done with the -e option of vgcreate.

#### Adding a new LV

The following creates a 500MB large LV named lvdata on any disk(s) of the VG vg01:

```
# lvcreate -n lvdata -L 500 vg01
```

You cannot specify a PV with lvcreate. If you like to place the LV on a specific PV, then first create an LV of 0MB. It has no extents - it just exists.

```
# lvcreate -n lvdata vg01
```

Now extend the LV onto a certain disk:

```
# lvextend -L 500 /dev/vg01/lvdata /dev/dsk/c4t2d0
```

Now you can use newfs to put a FS onto the LV:

```
# newfs -F <fstype> /dev/vg01/rlvdata
```

where fstype is either hfs or vxfs.

**NOTE:** Nowadays it is recommended to use a VxFS (=JFS) file system.

## Modifying a PV / VG / LV

#### **Modifying a PV**

There are certain PV parameters that can be changed (see pvchange man page). A frequently used parameter is the IO timeout parameter. This parameter tells LVM how long to wait for disk transactions to complete before taking the device offline. This is accompanied by POWERFAILED messages on the console. Certain disk arrays need a higher timeout value than simple disks. To specify e.g. a timeout of 120 seconds do:

```
# pvchange -t 120 /dev/dsk/cXtXdX
```

The device driver's default is usually 30 seconds. Setting the IO timeout to 0 seconds restores this default:

```
# pvchange -t 0 /dev/dsk/cXtXdX
```

#### Modifying a LV

The most common modification task is the modification of the size of a LV. To increase a LV from 500MB to 800MB do:

```
# lvextend -L 800 /dev/vg01/lvdata [/dev/dsk/c5t0d0]
```

**NOTE:** You may get the following error:

```
lvextend: Not enough free physical extents available. Logical volume "/dev/vg01/lvdata" could not be extended. Failure possibly caused by contiguous allocation policy. Failure possibly caused by strict allocation policy
```

The reason for that is exactly one of the above.

If the LV has been extended successfully you need to increase the FS that resides on that LV:

Without OnlineJFS you have to umount the FS first:

```
# umount /dev/vg01/lvdata
# extendfs /dev/vg01/rlvdata
# mount /dev/vg01/lvdata <mountpoint>
```

With OnlineJFS you do not need to umount. Use fsadm instead:

```
# fsadm -b <new size in KB> <mountpoint>
```

**NOTE:** Reducing a LV without OnlineJFS is not possible. You have to backup the data, remove and recreate the LV, create a new FS and restore the data from the backup into that FS.

With OnlineJFS you can try to reduce the FS using fsadm specifying the new size in KB. Due to some design limitations this often fails with JFS 3.1 and older. **After** fsadm successfully reduced the FS you can use lyreduce to reduce the underlying LV:

```
# lvreduce -L <new size in MB> /dev/vg01/lvdata
```

For details regarding JFS and OnlineJFS consult the <u>JFS Chapter</u>.

To change the **name of a LV** you can simply rename the LV devicefiles:

```
# umount /dev/vg01/lvol1
# mv /dev/vg01/lvol1 /dev/vg01/lvdata
# mv /dev/vg01/rlvol1 /dev/vg01/rlvdata
# mount /dev/vg01/lvdata <mountpoint>
```

There are several other characteristics of an LV that can be modified. Most commonly used are allocation policy, bad block relocation and LV IO-timeout. For details look at the lvchange man page.

## Modifying a VG

The vgchange command can be used to (de)activate a VG. Certain parameters like max\_pe (see above) cannot be changed without recreating the VG.

In order to rename a VG you have to export and re-import it:

```
# umount /dev/vg01/lvol1
# umount /dev/vg01/lvol2
...
```

**NOTE:** If you are dealing with a large amount of disks i recommend to use the "-f outfile" option with vgexport and vgimport. See section <u>Importing and exporting VGs</u> for details.

**NOTE:** Starting with LVM commands patch <u>PHCO 24645</u> (UX 11.00) or <u>PHCO 25814</u> (UX 11.11) vgcreate and vgimport will check for the uniqueness of the group file's minor number.

```
# vgcfgbackup vgnew
```

For details regarding vgchange look at the man page. vgexport/vgimport is described below in greater detail.

## Removing a PV / VG / LV

#### Remove an LV

```
# umount /data
# lvremove /dev/vg01/lvsap
```

#### Remove a PV from a VG

```
# vgreduce vg01 /dev/dsk/c5t0d0
```

#### Remove a VG

umount any LV of this VG, deactivate and export it:

```
# umount /dev/vg01/lvol1
# umount /dev/vg01/lvol2
...
# vgchange -a n vg01
# vgexport vg01
```

**NOTE:** vgremove is not recommended because you need to remove all LVs and PVs from the VG before you could use vgremove. This is not necessary with vgexport. Additionally vgexport leaves the LVM structures on the disks untouched which could be an advantage if you like to re-import the VG later.

# Moving physical extents

It is only possible to move PEs within a VG. In order to move data across VGs you need to use commands like dd, cp, mv, tar, cpio, ...

There is a command available that allows you to move LVs or certain extents of a LV from one PV to another - pvmove(1M). It is usually used to "free" a PV, i.e. to move all LVs from that PV in order to remove it from the VG. There are several forms of usage:

In order to move all PEs from c0t1d0 to the PVs c0t2d0 and c0t3d0:

```
# pvmove /dev/dsk/c0t1d0 /dev/dsk/c0t2d0 /dev/dsk/c0t3d0
```

In order to move all PEs of Ivol4 that are located on PV c0t1d0 to PV c1t2d0:

```
# pvmove -n /dev/vg01/lvol4 /dev/dsk/c0t1d0 /dev/dsk/c0t2d0
```

**ATTENTION:** pvmove is not an atomic operation. Furthermore the command moves data extent by extent and is easily interruptable. If this happens, then the configuration is left in some weird inconsistent state showing an additional pseudo mirror copy for the extents in question. This can be cleaned up **only** using the lvreduce command (Use *lvreduce -m 0 LV* if the LVs were unmirrored and *lvreduce -m 1 LV* if they were mirrored before starting the pvmove; there's no need to specify a PV here).

If MirrorDisk/UX is installed it is usually saver and faster to use mirroring as an alternative to pvmove. In order to move lvol4 from PV c0t1d0 to c0t2d0 just mirror it to c0t2d0 and remove the mirror from c0t1d0 afterwards:

```
# lvextend -m 1 /dev/vg01/lvol4 /dev/dsk/c0t2d0
# lvreduce -m 0 /dev/vg01/lvol4 /dev/dsk/c0t1d0
```

## Importing and exporting VGs

The functionality of exporting VGs allows you to remove all data concerning a dedicated VG from the system without touching the data on the disks. The disks of an exported VG can be physically moved to another system and the VG can be imported there. Exporting a VG means the following: remove the VG and corresponding PV entries from /etc/lvmtab and remove the VG directory with their device files in /dev. Again - the data on the disks is left unchanged.

Since the structural layout of the LVM information on disk has not changed throughout the HP-UX releases you can import a VG that has been created on a UX 10.20 system e.g. on a UX 11.11 system.

vgexport has a -m option to create a so called *mapfile*. This ascii file simply contains the LV names because they are not stored on the disks. You need a mapfile if you do not have the standard names for the LV device files (lvol1, lvol2, ...).

Here's the procedure to export a VG on system A and import it on system B:

#### on system A:

Umount all LVs that belong to the VG and deactivate it:

```
# vgchange -a n vgXX
```

#### Export the VG:

```
# vgexport -v -m /tmp/vgXX.map vgXX
```

Now all information about vgXX has been removed from system A. The disks can now be moved to system B and the VG can be imported there:

#### on system B:

Create the directory for the LV device files and the group file. It is important to choose a minor number that is unique on system B.

**NOTE:** Starting with LVM commands patch <a href="PHCO\_24645">PHCO\_24645</a> (UX 11.00) or <a href="PHCO\_25814">PHCO\_25814</a> (UX 11.11) vgcreate and vgimport will check for the uniqueness of the group file's minor number.

Now copy the mapfile from system A and import the VG:

```
# vgimport -v vgXX -m /tmp/vgXX.map /dev/dsk/c1t0d0 /dev/dsk/c1t1d0
```

**NOTE:** The PV device files may be different on system B compared to system A.

If you have a bunch of disks in the VG you may not want to specify each of them within the argument list of vgimport. Using the -s option with vgexport/vgimport lets you get around this:

```
# vgexport -v -s -m /tmp/vgXX.map vgXX
```

If you specify -s in conjunction with the -m option vgexport simply adds the VG-ID to the mapfile:

```
# cat /tmp/vgXX.map
VGID bfb13ce63a7c07c4
1 lvol1
2 lvol2
3 lvsap
4 lvdata
```

When using the -s option with the vgimport command on system B all disks that are connected to the system are scanned one after another. If the VG-ID listed in the mapfile is found on the header of a disk this disk is included automatically into the VG Here's the appropriate vgimport command:

```
# vgimport -v -s -m /tmp/vgXX.map vgXX
```

So you do not have to specify the PVs anymore.

**ATTENTION:** On systems using data replication products like BusinessCopy/XP, ContinousAccess/XP, EMC SRDF or EMC Timefinder it may be impossible to reliably identify the correct list of PVs using this VG-ID mechanism. You should specify the list of PVs explicitely here. The newly introduced –f option for vgimport helps to specify large PV lists on the command line (see man page). The -f Option is only available as of UX 11.X. For UX 11.00 you need LVM commands patch PHCO 20870 or later.

## Mirror Disk/UX

# **Basic functionality**

To be able to mirror LVs you need to purchase the product MirrorDisk/UX. Its important to remember that LVs are mirrored - not PVs. Especially the LVM header is not mirrored because it does not belong to the LV. You can have 1 or 2 mirror copies.

Here's how to mirror an existing LV to a specific PV:

```
# lvextend -m 1 /dev/vg01/lvol1 /dev/dsk/c1t0d0
```

**NOTE:** Ivextend allows either to specify the size of a LV (-L or -l) OR the number of mirror copies (-m). You cannot specify both within one command.

lvdisplay shows a mirrored LV like this:

To reduce the mirror (from PV c1t6d0):

```
# lvreduce -m 0 /dev/vg01/lvol1 /dev/dsk/c1t6d0
```

**ATTENTION:** If the LV uses the *distributed allocation policy* (aka *extent based striping*) you need to specify **all** PVs that you want to remove the mirror copy from. There is not (yet) an option that lets you specify the PVG as argument to lvreduce but there will be a LVM commands patch (maybe mid 2002). To check if the LV uses distributed allocation policy:

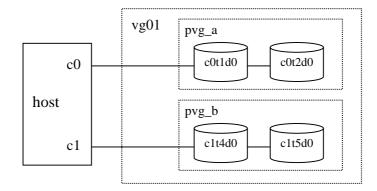

```
# lvdisplay /dev/vgXX/lvXX | grep Allocation
should show "distributed".
```

**NOTE:** Extending a mirrored LV works exactly like extending a non-mirrored LV. Ivextend enlarges both mirror copies. The LV allocation policies *strict* or *PVG-strict* ensure that the mirrors reside on independent disks or PVGs respectively.

# **Physical Volume Groups - PVGs**

If there are multiple host bus adapters (SCSI or fibre channel) available on the system it is useful in terms of high availablility to have mirror copies located on different adapters. The strict allocation policy for mirrored LVs guarantees that the mirror copy will not be placed on the same disk but it could be placed on a disk that is on the same adapter. The latter case can be avoided by using *physical volume groups*. A PVG is a subset of PVs within a VG that can be defined using -p option of vgcreate/vgextend or simply by creating an ascii file called /etc/lympyg.

Here's an example configuration:

If you want to be sure that the mirrors of LVs on e.g. c0t1d0 are not placed on c0t2d0 you need a lympyg file like the following:

```
# cat /etc/lvmpvg
VG /dev/vg01
PVG pvg_a
/dev/dsk/c0t1d0
/dev/dsk/c0t2d0
PVG pvg_b
/dev/dsk/c1t4d0
/dev/dsk/c1t5d0
```

As soon as this file is saved the configuration is active and vgdisplay will look like this:

Before mirroring a LV you need to set it's allocation policy to *PVG-strict*, e.g.:

```
# lvchange -s g /dev/vg01/lvol1
# lvdisplay /dev/vg01/lvol1 | grep Allocation
Allocation PVG-strict
```

For details look at the lympyg man page.

#### **Root Mirror**

To set up a mirrored root config you need to add an additional disk (e.g. c1t6d0) to the root VG mirror all the LVs and make it bootable.

1. Initialize the disk and add it to vg00:

```
# pvcreate [-f] -B /dev/rdsk/c1t6d0
# vgextend vg00 /dev/dsk/c1t6d0
```

2. Mirror the LVs using Ivextend:

```
\# lvextend -m 1 /dev/vg00/lvolX /dev/dsk/c1t6d0
```

If you want to use a shell loop to extend automatically, use e.g.:

3. **Important:** Configure LIF/BDRA, according to the <u>LIF/BDRA Configuration</u> <u>Procedure</u> at the end of this chapter.

4. Specify the mirror disk as alternate boot path in stable storage:

```
# setboot -a <HW-Path of mirror>
```

To determine the hardware path use e.g. ioscan:

5. Add the new mirror boot device to /stand/bootconf, e.g.:

```
1 /dev/dsk/c0t6d0 (original boot device)
1 /dev/dsk/c1t6d0 (new mirror boot device)
```

If you like to remove the mirror again, you need to use lyreduce:

```
# lvreduce -m 0 /dev/vg00/lvolX /dev/dsk/c1t6d0
```

Of course, this can also be done automatically using a shell loop, e.g.:

# **PV Links (Alternate Paths)**

Physical Volume Links (aka PV Links or Alternate Links) are a High Availability Feature of LVM which allows to configure multiple links (HW paths) to the same PV for redundancy. One of them is considered as the primary link while the others act as alternate links. If LVM detects the primary link beeing unavailable as a consequence of a failure (e.g. of a SCSI/FC card/cable) it re-routes IO traffic to the first available alternate link.

NOTE: It is the order in /etc/lymtab that defines the default order in which the links are used.

# **Configuring PV Links**

The following example shows how to create a VG with a disk having an alternate link. First check the available disk devices using ioscan:

disk	1	0/0/2/1.6.0	sdisk CLAIMED	DEVICE	SEAGATE ST39102LC
			/dev/dsk/c2t6d0	/dev/rdsk/d	22t6d0
disk	2	0/12/0/0.0.0	sdisk CLAIMED	DEVICE	SEAGATE ST118202LC
			/dev/dsk/c4t0d0	/dev/rdsk/c	24t0d0
disk	3	0/12/0/0.1.0	sdisk CLAIMED	DEVICE	SEAGATE ST118202LC
			/dev/dsk/c4t1d0	/dev/rdsk/d	:4t1d0
disk	13	0/12/0/0.2.0	sdisk CLAIMED	DEVICE	SEAGATE ST118202LC
			/dev/dsk/c4t2d0	/dev/rdsk/d	:4t2d0
disk	6	0/12/0/1.0.0	sdisk CLAIMED	DEVICE	SEAGATE ST118202LC
			/dev/dsk/c5t0d0	/dev/rdsk/d	:5t0d0
disk	7	0/12/0/1.1.0	sdisk CLAIMED	DEVICE	SEAGATE ST118202LC
			/dev/dsk/c5t1d0	/dev/rdsk/d	:5t1d0
disk	12	0/12/0/1.2.0	sdisk CLAIMED	DEVICE	SEAGATE ST118202LC
			/dev/dsk/c5t2d0	/dev/rdsk/c	25t2d0
disk	19	0/12/0/1.3.0	sdisk CLAIMED	DEVICE	SEAGATE ST118202LC

From cabling or cmpdisks utility (see below) we know that c4t1d0 and c5t1d0 identify the same disk.

Extend vg01 using one of the device files:

```
# pvcreate [-f] /dev/rdsk/c4t1d0
# vgextend vg01 /dev/dsk/c4t1d0
```

**NOTE:** Do not run pycreate on the other devicefile. Remember that it points to the same disk and this disk has already been pycreated.

This is how vgdisplay and pvdisplay report alternate links:

```
# vgdisplay -v vg01
. . .
   --- Physical volumes ---
  PV Name
                               /dev/dsk/c4t0d0
  PV Name
                               /dev/dsk/c5t0d0 Alternate Link
   PV Status
                               available
                               542
   Total PE
                               99
   Free PE
   Autoswitch
                               On
   PV Name
                               /dev/dsk/c4t1d0
   PV Name
                               /dev/dsk/c5t1d0 Alternate Link
   PV Status
                               available
   Total PE
                               542
   Free PE
                               0
   Autoswitch
                               On
# pvdisplay /dev/dsk/c4t1d0
--- Physical volumes ---
PV Name
                            /dev/dsk/c4t1d0
                            /dev/dsk/c5t1d0 Alternate Link
PV Name
VG Name
                            /dev/vg01
PV Status
                            available
Allocatable
                            yes
VGDA
                            2
Cur LV
                            2
PE Size (Mbytes)
                            32
```

Autoswitch	On
IO Timeout (Seconds)	default
Stale PE	0
Allocated PE	542
Free PE	0
Total PE	542

**IO Timeout:** The time that LVM retrys a link failed link is called *PV timeout* and can be specified using pvchange:

```
# pvchange -t 120 /dev/dsk/cXtXdX
```

sets the timeout to 2 minutes. The default is 0, which causes LVM to use the device driver's default (usually 30 sec).

**Autoswitch:** With autoswitch flag on (default) LVM always switches back to the primary link if it becomes available again. Otherwise the same link is used until the next failure.

## **Changing PV Link order**

To make an alternate link become the primary link (manual switch) use pvchange:

```
# pvchange -s <alternate>
```

To change it permanently (across VG deacivation/reactivation) you have to change the order in /etc/lvmtab:

```
# vgreduce vg01 <primary>
Device file path "/dev/dsk/c0t1d0" is a primary link. Removing
primary link and switching to an alternate link.
# vgextend vg01 <primary>
```

# **Utility cmpdisks**

cmpdisks is an unofficial shell script that collects information about all disks that can be seen on a system. It displays a sorted list of disks and their corresponding HW paths. cmpdisks works across multiple systems and is therefore very useful for ServiceGuard environments. It recognizes LVM and VxVM devices, also on Itanium systems.

Here's an example output for two nodes connected to shared storage:

```
grcdg319:c5t1d0 0630309352-0968061502 0/12/0/1.1.0 HP/C5447A (0x02/vgsap) hprtdd32:c4t1d0 0630309352-0968061502 0/6/0/0.1.0 HP/C5447A (0x02/vgsap) hprtdd32:c5t1d0 0630309352-0968061502 0/6/0/1.1.0 HP/C5447A (0x02/vgsap) 2 grcdg319:c4t0d0 0630309352-0968061503 0/12/0/0.0.0 HP/C5447A (0x02/vgsap) 2 grcdg319:c5t0d0 0630309352-0968061503 0/12/0/1.0.0 HP/C5447A (0x02/vgsap) 2 hprtdd32:c4t0d0 0630309352-0968061503 0/6/0/0.0.0 HP/C5447A (0x02/vgsap) 2 hprtdd32:c5t0d0 0630309352-0968061503 0/6/0/0.0.0 HP/C5447A (0x02/vgsap) 2 hprtdd32:c5t0d0 0630309352-0968061503 0/6/0/1.0.0 HP/C5447A (0x02/vgsap) 2 hprtdd32:c5t0d0 0630309352-0968061503 0/6/0/1.0.0 HP/C5447A (0x02/vgsap) 2 hprtdd32:c5t0d0 0630309352-0968061503 0/6/0/1.0.0 HP/C5447A (0x02/vgsap) 2 hprtdd32:c5t0d0 0630309352-1002790984 2 hprtdd32:c4t2d0 0630309352-1002790983 0/12/0/0.2.0 HP/C5447A (n/a) 2 hprtdd32:c4t2d0 0630309352-1002790983 0/6/0/0.2.0 HP/C5447A (n/a)
```

In the output above you can see:

- One non-shared disk in vg00 for each node.
- Two shared disks, each having one alternate link in shared VG vgsap on each node.
- One shared disk without alternate link that is not part of a VG.

# Offline Diagnostic Environment (ODE)

You need the ODE to be able to do HW troubleshouting in the case the system is not able to boot. The ODE files are LIF files that should be installed in the LIF volume on any bootable disk.

With Diagnostics installed (check with swlist OnlineDiag or simply type sysdiag) you can find the ODE files in a regular file:

**ATTENTION:** The file updatediaglif**2** is only for pure 64bit systems (e.g. N-Class). For 32bit systems or systems that support both CPU types (e.g. K-Class) use the file updatediaglif.

The Online Diagnostics bundle can be found on the Support Plus Media. You can write the ODE files to the LIF volume as follows:

(the -p option preserves the specified file so that it is not overwritten)

If you are setting up a mirrored root config you need to install the ODE files also on the mirror disk else you don't have ODE utilities like MAPPER2 if you booted there.

# LVM and MC/ServiceGuard (Cluster LVM)

In a ServiceGuard environment you have one or more VGs that have disks on the shared bus which can be accessed from multiple systems in the cluster. So it is very important to guarantee that a VG is active only on one node at a time or you will easily end up with inconsistant or corrupted data.

A VG that should be accessable from multiple nodes needs special treatment. You have to ensure that each node has current information about the VG, i.e:

- /etc/lvmtab
- /dev/vgXX/\*
- /etc/lvmconf/vgXX.conf

Any changes to the VG that would affect these files need to be updated to all other nodes that could potentially activate the VG.

The following table shows which configuration changes affect which files:

configuration change	affects				
comiguration change	/etc/lvmtab	/dev/vgXX/	/etc/lvmconf/		
adding/removing a PV from the VG	Yes	No	Yes		
adding/removing a LV from the VG	No	Yes	Yes		
changing LV/PV characteristics (like size)	No	No	Yes		

#### Example: Adding a disk to a cluster VG

- On the node where the VG is activated:
  - 1. Add the PV to the VG as usual:

```
# pvcreate [-f] /dev/rdsk/cXtXdX
# vgextend vgXX /dev/dsk/cXtXdX
```

2. Generate a map file:

```
# vgexport -p -s -m /tmp/vgXX.map vgXX
```

3. Use ftp or rcp to distribute the mapfile (/tmp/vgXX.map) to the other nodes.

- On all other nodes where the VG is not activated:
  - 1. Remember the VG minor number:

```
# 11 /dev/vgXX/group
```

2. If the VG does already exist, export it first and then import it:

```
# vgexport vgXX
# mknod /dev/vgXX/group c 64 0xXX0000
# vgimport -s -m /tmp/vgXX.map vgXX
```

**NOTE:** You may also use the "-f outfile" option of vgexport/vgimport where outfile contains a list of all devicefiles belonging to the VG. See section Importing and exporting VGs for details.

3. Backup the LVM configuration:

```
# vgchange -a r vgXX
# vgcfgbackup vgXX
# vgchange -a n vgXX
```

See the ServiceGuard Chapter for details.

# Replacing a Failed LVM Disk

In order to replace a failed disk you have to recover the original LVM header onto the new media. The command <code>vgcfgrestore(1M)</code> recovers the backup of the LVM header from the file system (/etc/lvmconf/vgxx.conf) to the disk. If data was mirrored you can easily sync it to the new disk. Otherwise you need to figure out which LVs have extents residing on that disk and recover the data from your backup.

**NOTE:** The replacement disk must be the same product ID as the replaced one. HP often uses different manufacturers for disks having the same product number. The hotswap procedures will not update the disk driver's internal information to that of the replaced disk. The replacement disk will have the same capacity and blocksize as the defective disk because they have the same product number. The only field that could be incorrect is the string specifying the vendor's name. This will not affect the behavior of the LVM. If it is desired to update the manufacturers' name, then the disk's volume group must be deactivated and reactivated.

Replacing a disk in a **ServiceGuard environment** makes no real difference. Even replacing a cluster lock disk is no problem, since the LVM configuration backup contains all needed information about it. This is true as long as vgcfgbackup was run after configuring the cluster. Consult the **ServiceGuard Chapter** if you are unsure.

**ATTENTION:** If this is an **Itanium** system (UX 11.20, UX 11.22, UX 11.23) you need to take care of the new disk partitioned layout. The first partition (cXtXdXs1) contains the EFI (100MB). The former LVM disk is now located at partition 2 of the disk (cXtXdXs2). For details on how to replace an Itanium root disk refer to the <u>Itanium Chapter</u>.

## Identifying the failed disk

First of all you have to figure out which disk actually failed. **Do not rely on the output of LVM's display commands only!** Especially in mirrored configurations you have to be very careful.

Here are some approaches how to check for typical symptoms of failed disks.

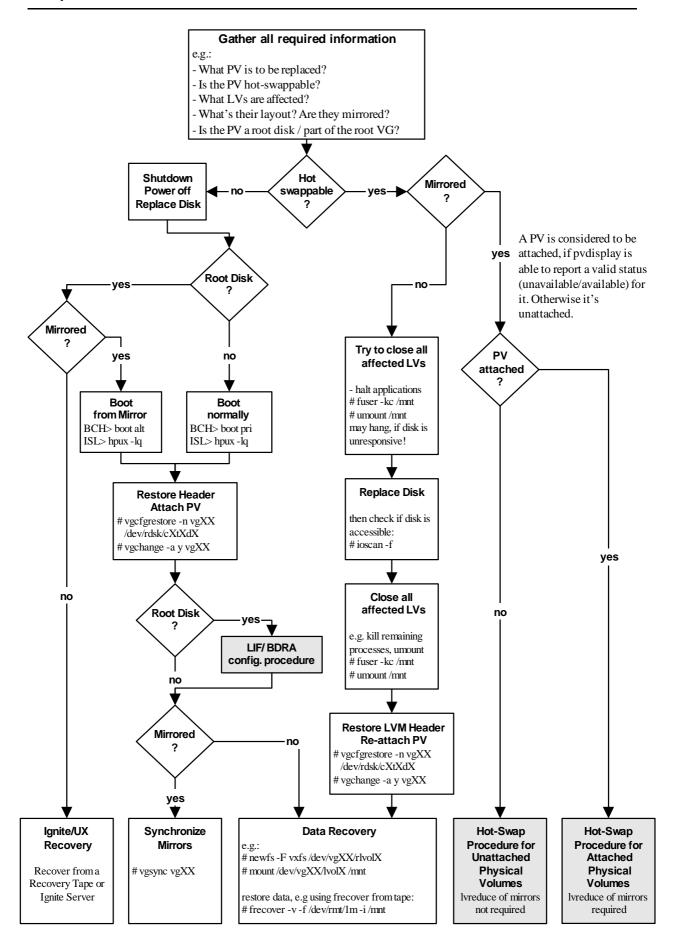

- Use the ioscan(1M) command (ioscan -fcdisk) to have a look at the disk's S/W state. Only disks in state CLAIMED are currently accessible by the system. Disks in other states like NO\_HW are of course suspicious. This is also true for disks that are completely missing in ioscan's result. If the disk is CLAIMED then at least its contoller is responding.
- The next step could be a test with diskinfo(1M) (diskinfo /dev/rdsk/cxtxdx). The reported size must be >0, otherwise the device is not ready for some reason.
- Although being more time consuming, trying to read the disk with dd(1) completely (dd if=/dev/rdsk/cXtXdX of=/dev/null bs=256K) or partially (dd if=/dev/rdsk/cXtXdX of=/dev/null bs=256K count=100) is also a useful indicator. No I/O errors must be reported here.
- Use hardware diagnostic tools (like MESA diagnostics, mstm/cstm commands) to get detailed diagnostic information about the disk. These tools offer the most conclusive information.

Last, but not least, **You must be sure about what disk is the defective one!** Starting any replacement procedure based on wrong assumptions can cause loss and corruption of data.

# **Disk Replacement Flow Chart**

The following flow chart is supposed to provide an overview about possible LVM disk replacement scenarios. The procedures for the most important case in HA environments (hotswappable and mirrored) are presented in detail later (<u>Hot-Swap Procedure for Attached Physical Volumes</u>, Hot-Swap Procedure for Unattached Physical Volumes).

## **Hot-Swap Procedure for Attached Physical Volumes**

**NOTE**: A physical volume is considered to be *attached*, if the pvdisplay command is able to report a valid status (unavailable/available) for it. Otherwise it's called *unattached*.

**ATTENTION:** As of today (HP-UX 11.23) the offical replacement procedure stipulates to reduce mirror copies from attached PVs before performing the actual replacement. However, there are other (unofficial) cookbooks allowing the replacement without this safety measure.

In this LVM chapter we only consider the official procedure to be supported. The reason is that there are potentially serious problems with replacing an attached device. Although the pvdisplay indicates the device is unavailable, LVM could still be trying to recover it. There is a possibility that a device that pvdisplay shows to be unavailable one moment could immediately appear to be available again just as the new device is being initialized in-place with vgcfgrestore. The consequences can be data corruption or obscure problems that can be difficult to track down, due to the LVM metadata on the device being improperly written. A seemingly plausable but also unsupported solution to this problem is to initialize (vgcfgrestore) the replacement disk in a different location (e.g. an unused slot in the storage system). Then replace the unavailable disk with the new one. This will work safely as long as LVM recognizes that the device is unavailable before the disk is replaced.

Follow these steps to replace a hot-swap disk module for *attached* Physical Volumes, which means that the disk was defective/unaccessible at the time the volume group was activated. Hot-swapping a disk which was defective during activation (*unattached*) requires a different sequence of commands. Skip to the alternative procedure, <a href="Hot-Swap Procedure for Unattached Physical Volumes">Hot-Swap Procedure for Unattached Physical Volumes</a>.

1. Reduce any logical volumes that have mirror copies on the faulty disk so that they no longer mirror onto that disk.

NOTE: Be advised to check first, what LVs have mirror extents allocated on the faulty disk (to be checked with pvdisplay –v /dev/dsk/cXtXdX). Then you should check for each found LV how it is mirrored (use lvdisplay –v /dev/vgXX/lvolX). If the mirror extents span more than one PV then it is highly recommended to specify all PVs with the lvreduce command that are in the "same mirror set of disks" as the faulty one. Otherwise LVM may pick the "wrong" disks for reduction, leading to undesired results (e.g. asymmetrical layouts). Take a note of this PV list, since you need this information later when you re-establish the mirror using lvextend.

```
# lvreduce -m 0 -A n /dev/vgXX/lvolX <list of PVs> (for 1 way mirroring)
or
# lvreduce -m 1 -A n /dev/vgXX/lvolX <list of PVs> (for 2 way mirroring)
```

where *list* of PVs is the list of devices determined according to the note above. We use the -A n option to prevent the lyreduce command from performing an automaticic vgcfgbackup operation, which is likely to get stuck on accessing a defective disk.

2. Replace the faulty disk. Please refer to the appropriate administration guide for instructions on how to replace the disk.

Do an ioscan on the replaced disk to insure that it is accessible (CLAIMED) and also as a double check that it is a proper replacement (see <u>note</u> above).

```
# ioscan -f /dev/dsk/cXtXdX
```

3. For fibre channel disks perform the replace\_dsk steps described in the section "*How to Replace Disks at Hosts with TachLite HBAs*" in the <u>Fibre Channel chapter</u>.

4. Restore the LVM configuration/headers onto the replaced disk from your backup of the LVM configuration.

```
# vgcfgrestore -n VG /dev/rdsk/cXtXdX
```

5. Attach the new disk to the active volume group with the vgchange command.

- 6. **Important:** If the disk is the mirror of a root disk, then you must configure the LIF/BDRA according to the <u>LIF/BDRA Configuration Procedure</u> at the end of this chapter.
- 7. Lvextend the mirrors back onto the replaced disk. This may take several minutes as it will have to copy all the data from the original copy of the data to the mirrored extents. The logical volume(s) are still accessible to users' applications during this command.

To check the progress of the synchronization you could use:

```
# lvdisplay -v $(find /dev/vgXY -type b) | grep stale | wc -l
```

A shell loop like this could be used to extend a bunch of lvols automatically:

```
# for lvol in lvol1 lvol2 lvol3 ... (specify any LV you need to mirror)
> do
> lvextend -m 1 /dev/vgXX/$lvol /dev/dsk/cXtXdX
> done
```

# **Hot-Swap Procedure for Unattached Physical Volumes**

Follow these steps to replace a hot-swap disk module for unattached physical volumes.

6. Replace the faulty disk. Please refer to the appropriate administration guide for instructions on how to replace the disk.

Do an ioscan on the replaced disk to insure that it is accessible (CLAIMED) and also as a double check that it is a proper replacement (see <u>note</u> above).

```
# ioscan -f /dev/dsk/cXtXdX
```

7. For fibre channel disks perform the replace\_dsk steps described in the section "How to Replace Disks at Hosts with TachLite HBAs" in the Fibre Channel chapter.

8. Restore the LVM configuration/headers onto the replaced disk from your backup of the LVM configuration.

```
# vgcfgrestore -n VG /dev/rdsk/cXtXdX
```

9. Attach the new disk to the active volume group with the vgchange command.

- 10. **Important:** If the disk is the mirror of a root disk, then you must configure the LIF/BDRA according to the <u>LIF/BDRA Configuration Procedure</u> at the end of this chapter.
- 11. Resynchronize the mirrors of the replaced disk. This may take several minutes as it will have to copy all the data from the original copy of the data to the mirrored extents. The logical volume(s) are still accessible to users' applications during this command.

```
# vgsync vgXY &
```

To check the progress of the synchronization you could use:

```
# lvdisplay -v $(find /dev/vgXY -type b) | grep stale | wc -l
```

# Removing a Ghost Disk using the PV Key

#### What is a Ghost Disk

You may come into a situation where you have to remove a PV from a VG that has failed or not even physically connected but still recorded in the lymtab. Such a PV is sometimes called a "ghost disk" or "phantom disk". You can get a ghost disk if the disk has failed before VG activation, maybe because the system has been rebooted after the failure.

If you cannot use vgcfgrestore to write the original LVM header back to the new disk because a valid LVM configuration backup file (/etc/lvmconf/vgXX.conf[.old]) is missing or corrupted you have to remove that PV from the VG (vgreduce) to get a clean configuration.

**NOTE:** In such situations the vgcfgrestore command may fail to restore the LVM header, complaining about a 'Mismatch between the backup file and the running kernel'. If you are 100% sure that your backup is valid you may override this check using the –R option.

In order to remove a PV from a VG you have to free it first, i.e. remove all logical extents from it. If the LVs on such a disk is not mirrored data is lost anyway. If it is mirrored you need to reduce the mirror before removing the PV.

A *ghost disk* is usually indicated by vgdisplay reporting more current PVs than active ones. Additionally LVM commands may complain about the missing PVs:

```
# vgdisplay vg01
vgdisplay: Warning: couldn't query physical volume "/dev/dsk/c0t11d0":
The specified path does not correspond to physical volume attached to
this volume group
vgdisplay: Couldn't query the list of physical volumes.

                            473
Free PE
                            Ω
Total PVG
```

Note that the PV c0t11d0 is still recorded in lymtab:

```
# strings /etc/lvmtab
/dev/vg01
/dev/dsk/c0t0d2
/dev/dsk/c1t2d2
/dev/dsk/c0t11d0
```

Running vgreduce with the -f option would remove all PVs that are "free", i.e there is no LV having extents on that PV. Otherwise - if the PV is not free - vgreduce -f reports an extent map to identify the associated LVs:

In this case Ivol1 is having extents on device c0t11d0. You have to remove these extents from the PV before you are allowed to actually remove the PV from the VG. If the LV is mirrored use the command Ivreduce to remove its mirrored extents. If the LV is unmirrored, data is lost anyway and you have to use Ivremove to delete the LV.

#### Check the LV state:

```
# lvdisplay -v /dev/vg01/lvol1
lvdisplay: Warning: couldn't query physical volume "/dev/dsk/c0t11d0":
The specified path does not correspond to physical volume attached to
  this volume group
lvdisplay: Couldn't query the list of physical volumes.

```

In this example you can see, that the LV in question is mirrored. One of its PVs is not attached to the VG, so its device file is unknown to LVM and displayed as "???". Addressing this PV is no longer possible using the device file name

# Removing a PV using its PV key

The PV key of a disk indicates its order in the VG. The first PV has the key 0, the second has the key 1, etc. This does not necessarily have to be the order of appearance in lymtab altough it is usually like that, at least when a VG is initially created.

The PV key can be used to address a PV that is not attached to the VG. This usually happens if it was not accessible during activation, e.g. due to a hardware or configuration problem.

**NOTE:** The PV may be unattached due to some temporary problem during VG activation which is no longer present. In this case you should try to re-activate the VG to force LVM to re-scan the devices listed in lymtab:

If the problem persists follow these steps to clear the situation:

1. Obtain the PV key using the -k option of lvdisplay:

Compared to the output above the ??? have been replaced with the PV key (= 0).

**NOTE:** You can use the xd(1) command to display the PV key because it is stored at a fixed position in the LVM header, exactly 8222 bytes from the beginning of the disk:

```
# xd -j8222 -N2 /dev/rdsk/c1t6d0
```

**NOTE:** Sometimes you see messages like **PV**[*X*] is **POWERFAILED** in syslog. In this case *X* is the PV key.

2. Reduce the mirror with the obtained key as argument:

```
# lvreduce -k -m 0 /dev/vg01/lvol1 0
```

3. After that the PV can be removed from the VG:

```
# vgreduce -f vg01
skip alternate link /dev/dsk/clt2d2
vgreduce: Couldn't query physical volume "/dev/dsk/c0t11d0":
The specified path does not correspond to physical volume attached to this volume group
PV with key 0 sucessfully deleted from vg vg01
Repair done, please do the following steps....:
```

- 1. save /etc/lvmtab to another file
- 2. remove /etc/lvmtab
- 3. use vgscan(1m) -v to re-create /etc/lvmtab
- 4. NOW use vgcfgbackup(1m) to save the LVM setup
- 4. Perform the above steps indicated above in order to remove the PV from the lymtab:

```
# mv /etc/lvmtab /etc/lvmtab.org
# vgscan -v
```

```
...
Scan of Physical Volumes Complete.

*** LVMTAB has been created successfully.

*** If PV links are configured in the system.

*** Do the following to resync information on disk.

*** #1. vgchange -a y

*** #2. lvlnboot -R
```

#### 5. Check the results:

```
# strings /etc/lvmtab
/dev/vg01
/dev/dsk/c0t0d2
/dev/dsk/c1t2d2
```

6. Re-activate the VG and backup the LVM config:

```
# vgchange -a y vg01
# vgcfgbackup vg01
```

If the LV was not mirrored, re-create the LV (lvcreate), create a FS on it (newfs) and recover your data from backup.

# Increasing the Root LV's size

Usually you cannot easily add space to the root LVs (/ or /stand) because they need to be contiguous. The following procedures work around this.

# **Using Ignite/UX**

The recommended and only supported procedure to add space to the root LVs is to use Ignite/UX, e.g. a *make\_tape\_recovery* Medium (refer to the <u>Ignite-UX chapter</u> for details). To create a recovery tape with Ignite/UX containg the entire root VG just insert a medium into the drive an run:

```
# make_tape_recovery -vA [ -d /dev/rmt/Xm ]
```

If for some reason the above does not apply you may use the unofficial (and also unsupported) procedure below.

# **Using the Unofficial Procedure**

Since the root LV has to be contiguous it is not possible to increase it because it is not the last LV on the root disk. Anyway - it is possible to do it without using Ignite-UX if there is an additional free disk available - c1t1d0 in the following example:

1. Create a new VG vgroot with c1t1d0:

2. Create LVs for boot, swap and root (in that order). Use at least the same size as in your original root VG:

- 3. Configure LIF and BDRA on c1t1d0 (see the LIF/BDRA Configuration Procedure).
- 4. Create LVs for /usr, /opt, /var, /tmp, /etc, /home, etc. Use at least the same size as in your original root VG:

```
# lvcreate vgroot
# lvextend -L 500 /dev/vgroot/lvol4
```

5. Create the file systems:

```
# newfs -F hfs /dev/vgroot/rlvol1
# newfs -F vxfs /dev/vgroot/rlvol3
# newfs -F vxfs /dev/vgroot/rlvol4
...
```

6. Mount the file systems:

```
# mkdir /new_root /new_usr /new_stand ... (Create mount points)
# mount /dev/vgroot/lvol1 /new_stand
# mount /dev/vgroot/lvol3 /new_root
# mount /dev/vgroot/lvol4 /new_usr
...
```

7. Copy the data, e.g. using find(1) with cpio(1):

```
# cd /
# find . -xdev -depth | cpio -pvdlmax /new_root
# cd /stand
# find . -xdev -depth | cpio -pvdlmax /new_stand
# cd /usr
# find . -xdev -depth | cpio -pvdlmax /new_usr
...
```

8. Modify the fstab in /new\_root/etc. Replace occurences of *vg00* with *vgroot*:

```
/dev/vgroot/lvol1 /stand hfs defaults 0 0 (new boot LV)
/dev/vgroot/lvol3 / vxfs delaylog 0 0 (new root LV)
/dev/vgroot/lvol4 /usr vxfs delaylog 0 0 (new/usr LV)
```

9. Change the device files for the root disk in /stand/bootconf to c1t1d0:

```
# vi /stand/bootconf
l /dev/dsk/c1t1d0
```

# vi /new\_root/etc/fstab

10. Configure disk c1t1d0 as boot path in stable storage and boot from it:

```
# setboot -b <HW path of c1t1d0>
# shutdown -r 0
```

11. When the system comes up again, backup vgroot's LVM Configuration:

```
# vgcfgbackup vgroot
```

12. And finally remove the old root VG if desired:

```
# vgchange -a n vg00
# vgexport vg00
```

#### If you like to rename vgroot to vg00:

1. Boot to LVM maintenance mode:

```
ISL> hpux -lm
```

2. Export vgroot and import it as vg00:

3. Activate vg00 and mount the files ystems:

```
# vgchange -a y vg00
# mount /dev/vg00/lvol3 /
# mount /dev/vg00/lvol1 /stand
# mount /dev/vg00/lvol4 /usr
```

4. Modify the fstab. Replace vgroot with vg00 again:

```
# vi /etc/fstab
```

#### 5. Reboot:

```
# shutdown -r 0
```

# LIF/BDRA Configuration Procedure

This subprocedure installs/updates information on disk that is **mandatory** for boot support. Therefore it is referenced from several other parts of this chapter.

1. Write LIF header and LIF files (ISL, AUTO, HPUX, LABEL):

```
# mkboot -l /dev/rdsk/cXtXdX
# lifls -l /dev/rdsk/cXtXdX (to ckeck it)
```

2. Write content of AUTO File:

(if autoboot is desired)

**NOTE:** By default, LVM enforces a quorum of >50% of a VG's PVs being available at activation time. If e.g. the root VG contains 2 PVs, then the system rejects to boot unless you disable the quorum check using the –lq option.

3. Install ODE files (may be skipped):

```
# cd /usr/sbin/diag/lif
```

```
# getconf HW_CPU_SUPP_BITS (the result is either 32, 32/64 or 64)
```

- # mkboot -b updatediaglif2 -p ISL -p AUTO -p HPUX -p LABEL /dev/rdsk/cXtXdX  $(if \, 64)$

(the -p option preserve the specified file so that it is not overwritten in LIF)

Refer to section Offline Diagnostics (ODE) if you have problems with this.

4. Write content of LABEL file, i.e set root, boot, swap and dump device:

**NOTE:** This step can be omitted if you replace a failed mirror disk. Then this information has already been restored by vgcfgrestore. To be sure to have the latest information on the disk just do the following steps.

```
# lvlnboot -r /dev/<rootVG>/lvol3
# lvlnboot -b /dev/<rootVG>/lvol1
# lvlnboot -s /dev/<rootVG>/lvol2
# lvlnboot -d /dev/<rootVG>/lvol2
# lvlnboot -v (to ckeck it)
```

## **Commands Overview**

command	desciption
vgcreate	create a new VG
vgdisplay	display information about the VG
vgchange	activate/deactive a VG or change parameter of a VG
vgextend	add a new PV to the VG
vgreduce	remove a PV from the VG
vgremove	remove a VG (better use vgexport)
vgcfgbackup	backup the LVM header of a disk to a file
vgcfgrestore	restore the LVM header from a file to a disk
vgexport	remove the info of a VG from the system
vgimport	create a previously exported VG on this system
vgscan	recontruct /etc/lvmtab from the LVM headers on disk
vgchgid	change the VG-ID of a VG (needed for XPs)
vgsync	synchronize all mirrored LVs in the VG
lvcreate	create a new LV
lvdisplay	display information about LV
lvchange	change characteristics of a LV
lvextend	increase the size of LV / add a mirror copy to LV
lvreduce	decrease the size of LV / remove a mirror copy from LV
lvremove	remove the LV
lvspit	split a mirror copy of a LV (results in a separate LV)
lvmerge	merge a splitted mirror copy of a LV
lvsync	synchronize a mirrored LV
lvlnboot	set info about root, boot, swap, dump LVs in the BDRA
lvrmboot	delete info about root, boot, swap, dump LVs from BDRA
pvcreate	initialize a new disk for LVM
pvdisplay	display information about PV within VG
pvchange	change characteristics of a PV
pvmove	move PEs of a LV from one PV to another
pvremove	remove LVM data structure from a PV
pvck	check or repair a physical volume in a VG

**NOTE:** All LVM commands are hard-linked to the same single executable, e.g.

```
# 11 -iF vg* lv* pv* nomwc*
     241 -r-sr-xr-x 31 root
